Résumé

Une fouille de sauvetage archéologique a été réalisée en 1991 sur le site dorsétien GhGk-63 situé dans la municipalité de Kuujjuarapik, dans la partie sud-est de la baie d'Hudson. Ce projet représente la deuxième saison consécutive d'activités de sauvetage sur ce site. Les fouilles ont été organisées à la requête de la municipalité dans le but de sauvegarder l'information archéologique mise en péril par l'éventuelle utilisation de l'emplacement pour la formation d'opérateurs de véhicules lourds.

Le site GhGk-63 comprend trois habitations semi-souterraines, six structures de tente et quatre aménagements particuliers, comprenant une cache à nourriture, une cache d'objets lithiques et deux caches suggérées. Les habitations semi-souterraines, deux des structures de tente, la cache à nourriture et la cache d'objets lithiques se trouvent dans un champ de blocs formant la partie nord du site. Les autres structures de tente et aménagements sont situés dans la partie sud du site, composée de dépôts humiques et sableux.

Un total de 82,70 m^2 a été fouillé dans la partie sud du site. Cette fouille a été amorcée l'année précédente autour de deux structures de tente, qui ont été complétées cette année en plus de l'excavation complète d'une troisième structure. La fouille a permis la collecte de 7 721 objets lithiques, desquels 340 sont des outils. Ces derniers, incluant des pointes, couteaux, grattoirs et microlames, sont de fonctions diverses et reflètent une grande variété d'activités domestiques et de subsistance. Plus de 800 ossements d'animaux et 16 échantillons de charbon de bois ont aussi été récupérés. Les datations au ^{14}C révélées par deux de ces échantillons ainsi que la date obtenue lors des travaux antérieurs, confirment que le site a été occupé par des groupes dorsétiens moyens entre 50 av. J. C. et 240 de notre ère.

Les composantes excavées suggèrent quelques phases successives d'occupation du site. Des occupations de courtes durées pendant les saisons chaudes par de petits groupes composés d'une ou deux familles sont suggérées. De plus, la relative homogénéité de la matière première dans la collection lithique tend à indiquer une occupation continue à travers le temps par une population locale.

Il est estimé que la grande majorité du matériel culturel présente sur le site GhGk-63 a été récupérée, donc aucune autre intervention de terrain n'est recommandée. Les données recueillies sont d'une grande importance pour améliorer la connaissance de la culture dorsétienne du Nunavik. Ainsi, une analyse exhaustive de ces données est fortement recommandée.

Acknowledgments

The archaeological salvage project carried out at the GhGk-63 site was greatly facilitated by the co-operation of a number of local officials of the Municipality of Kuujjuarapik. Our thanks, first, to Sappa Fleming, past mayor of the municipality, who made available to the field crew a municipal truck for daily transportation between the village and the site. We are also indebted to Robert Fleming, President of the Sakkuq Landholding Corporation, who arranged accommodations for the project director, and Lucassie Cookie, Manager of Sakkuq, who acted as local project manager. Our gratitude as well to Peter Papialuk, Assistant to the Municipal Secretary-Treasurer, for providing access to the truck during weekends.

The project was funded by a grant arranged through contract with the Vice-présidence Environnement of Hydro-Québec.

The Avataq Cultural Institute gratefully acknowledges the support and assistance of the above individuals and Hydro-Québec in the GhGk-63 archaeological salvage project.

1.0 Introduction

This report concerns the archaeological salvage project conducted in 1991 at the GhGk-63 site, a partly disturbed Dorset settlement. The site is located in the Municipality of Kuujjuarapik, near the mouth of the Great Whale River, southeastern Hudson Bay (Figure 1). It is situated on the southeastern slope of a low bedrock hill, approximately 900 m north of the village and about 1km east of the coast.

The project represents the second season of salvage excavations at the site. Both of these exercises were carried out at the request of the Municipality of Kuujjuarapik. The 1990 excavations were undertaken in order to rescue archaeological resources threatened by the proposed renewed exploitation of an abandoned gravel pit in the site for the construction of new houses in the village. However, as the remaining gravel in the site was subsequently found to be of inadequate quality for this work, these exploitation plans were cancelled later that summer. Last year's project was organised on the basis of information received regarding the possible use of the site locality for the training of heavy equipment operators. It was implemented, specifically, to mitigate the future impacts of such training on the site.

Field activities were carried out over the 2-week period between June 12 and 26. The field crew included Lizzie Fleming, Johnny Cookie and Harry Fleming, all from Kuujjuarapik. The latter individual was replaced during the second week of work by Caroline Weetaluktuk, also from the village. The crew was directed by Daniel Gendron, Assistant Director of Avataq's Archaeology Department.

2.0 Description of the GhGk-63 site

The GhGk-63 site is divided into 2 sections of different geomorphological character. The northern section occupies a small boulder field while the southern section is composed of discontinuous humus and sand deposits directly underlain by bedrock (c.f., Appendix 4). The southeastern portion of the boulder field was destroyed in 1986 by gravel extraction work. The zones immediately west and south of the gravel pit were also disturbed by this work.

The site is bounded on the north and west by exposed bedrock and, on the east, by marine terraces and the gravel pit. Its southern limits are formed by eroded terraces bordering a relatively wet zone. As defined, the site covers a surface area of approximately 4,000 m^2 and varies in altitude from 26 to 32 m.a.s.l.

The site consists of 9 habitation structures and 4 exterior features (Table 1). The habitations include 3 semi-subterranean dwellings, represented by shallow, sub-rectangular depressions in the boulder field, and 6 tent rings of various form. One of the tent rings is situated in the boulder field and another on the southeastern edge of this formation. The 4 others are located in the southern section of the site.

The exterior features include a food cache (i.e., Feature I) and a cache of lithic preforms and core fragments (i.e.,Feature II), situated in the boulder field. Features III and IV are composed of rock concentrations located in the central portion of the southern section of the site. Both are provisionally interpreted as representing the remains of caches.

The boulder field section of GhGk-63 was discovered during the course of the 1986 archaeological survey of the new solid waste disposal site proposed for the Municipality of Kuujjuarapik (c.f., Avataq, 1987). At that time the 3 semi-subterranean dwellings and 1 of the 2 tent rings then registered in the site were intensively tested. Although testing of the structures proved negative, surface-collecting in the disturbed zone along the southern periphery of the gravel pit produced a small number of lithic artifacts. This collection included a burin which, combined with the boulder field context of the semi-subterranean dwellings, suggested a Pre-Dorset affiliation for the site.

Table 1. Summary of Cultural Features Indentified in the GhGk-63 site.

A. Habitation Structures

Number	Type	Form	Dimensions (m)	Remarks
1	tent ring	oval	3.50 x 3.0	contains a mid-passage, 75 cm in width and oriented east-west
2	tent ring	rectangular	2.50 x 2.10	
3	semi-subterranean	sub-rectangular	2.80 x 2.20 D: 0.5	
4	semi-subterranean	sub-rectangular	2.70 x 2.20 D: 0.5	
5	semi-subterranean	sub-rectangular	2.70 x 2.30 D: 0.5	cointains a posible hearth
6	tent ring	oval	3.80 x 3.0	partially overlapped by Structure 7
7	tent ring	bilobate	4.20 x 2.60	contains a mid-passage, 60 cm in width and oriented east-west
8	tent ring	oval	3.40 x 2.60	
9	tent ring	oval	5.20 x 5.0	entrance roughly 1.0 m in width, oriented toward the east

B. Exterior Features

Number	Type	Dimensions (m)	Remarks
I	food cache	2.0 x 1.20	
II	lithic cache	2.0 x 1.80	contains a large number of preforms and cores
III	rock concentration	1.60 dia.	possible cache
IV	rock concentration	3.40 x 2.30	possible cache

m: metre
dia.: diametre
D: depth

The southern section of GhGk-63 was identified in July, 1990, during an emergency evaluation of the site. As the site was then endangered by plans for gravel extraction, a salvage excavation project was rapidly organized and conducted in this section later that summer, between August 15 and 19 (c.f., Avataq, 1991). This brief project allowed the excavation of 44.50 m^2, test-pitting in the disturbed zone south of the gravel pit included. Almost all of Structure 8 and the greater part of Structures 6 and 7 were excavated. Also, Features II and III were completely excavated and Feature IV was sampled.

The above excavations yielded 4,514 lithic specimens, including 322 tools and tool fragments. The tools, comprising a wide variety of functional types, indicated that the site was occupied by groups of the Dorset culture rather than by earlier Pre-Dorset groups. In addition, a charcoal sample obtained from Structure 6 provided a radiocarbon date of 2050±100 B.P. (BGS 1476), or 50 B.C. for the occupation of this structure (Avataq, 1991:9).

3.0 Field Techniques

The field techniques applied in the 1991 project were similar to those practised in the site the previous year. The alpha-numerical grid system established in 1990 was re-installed and excavation proceeded by square metre. The north and east co-ordinates and stratigraphic level were recorded for each identified tool and tool fragment recovered from the excavation units. Lithic waste flakes and bone remains were collectively registered according to quadrant (i.e., 50 x 50 cm) and stratigraphic level in the units.

The location of all lithic artifacts and other occupational data found in the excavation units was plotted on millimetric graph paper at a scale of 1:10. Representative stratigraphic profiles were also drawn at the same scale. The habitation structures, features, certain profiles and other details were photographed in colour and black and white prints and in slides.

4.0 Project Results

A total of 82.70 m^2 was excavated in the southern section of the site in 1991. Of this total, 52 m^2 were excavated in the central portion of the section and 30.70 m^2 in the Structure 9 area (c.f., Appendix 4). The excavations in the central area encompassed the northern periphery of Structures 6 and 7, the western half of Feature IV and the interstructural zones between this feature and Structure 6 and between Structures 7 and 8. Excavations on the northwestern edge of Structure 7 included a vague alignment of rocks which was interpreted in 1990 as a tent ring (c.f., Avataq, 1991, Appendix 3, Structure 10). However, the suggested alignment was non-existent and the interpretation of a habitation structure in this zone was shown to be erroneous.

4.1 Stratigraphy

A generally uniform stratigraphic sequence was revealed throughout the central excavation area. As illustrated in Avataq (1991, Appendix 4), the upper units of the sequence consist of surface vegetation and an underlying layer of sandy humus (i.e., Levels I and II). The vegetation, dominated by mosses and grass, was discontinuous in the eastern part of the area. It attained a maximum thickness of 10 cm west of Structure 7, in a zone frequently saturated by surface run-off. The humus varied in thickness from 1 to 5 cm and was underlain by relatively fine, yellowish sand (i.e. Level III), deposited on bedrock. Level III ranged in thickness from 2 to 30 cm. At certain places in the zone between Structures 7 and 8 the sand was heavily impregnated with burnt organic matter.

The stratigraphy in the Structure 9 area differed somewhat from that in the central area. These differences relate to the location of the structure in a markedly wetter zone. In this instance Level I included a layer of sphagnum which, attaining a maximum thickness of 20 cm, completely encircled the structure and extended into its western portion (c.f., Appendix 6). A thin mantle of low moss and grass covered the other portions of the tent ring. Levels II and III were composed of humus and sand layers and, exterior to the habitation, were high in sphagnum content. These levels varied in thickness from 3 to 8 cm and 2 to 20 cm, respectively.

4.2 Structures

With few exceptions the rocks defining Structures 6, 7 and 9 and Feature IV were associated with Level III. The exceptions occurred on the surface of the bedrock.

Structure 6 consists of an oval configuration of irregularly spaced rocks (c.f., Appendix 5). The full contour of the structure is somewhat obscure, its western segment being partially overlapped by Structure 7. Structure 6, measuring 3.80 x 3.0 m, lacks definable interior features. However, several concentrations of charcoal associated with a small cluster of rocks on the northern periphery of the tent ring suggest a hearth area. This suggestion is supported in part by the distribution of lithic artifacts in the structure, the majority of which were recovered in the vicinity of the charcoal concentrations.

Structure 7 is bilobate in form and measures 4.20 x 2.60 m. It contains a relatively well-preserved mid-passage composed of flagstone paving bordered by rectangular blocks. The mid-passage, oriented east-west, is 60 cm in width by 2.30 m in length.

A dense concentration of rocks occupies a depression in the bedrock immediately west of Structure 7. This concentration covers approximately 4 m^2 and exceeds 30 cm in thickness. It is divisible into 3 courses of rocks separated by lenses of Level III sand. The uppermost course is partly incorporated in Structure 7. Significant quantities of charcoal and numerous lithic artifacts occurred in the sand lenses separating the upper 2 courses. The lowest sand lens contained an appreciable number of animal bones. The lithics, charcoal and bones were distributed throughout the depression to the eastern edge of Structure 8, roughly 5 m west of the rock concentration.

Structure 9 is well-defined, oval in shape and measures 5.20 x 5.0 m (c.f., Appendix 6). The entrance of the structure is suggested by a gap about 1 m wide in the eastern segment of the tent ring. Two clusters of rocks in the northern half of the habitation also suggest interior features of undetermined function. Several small fragments of charcoal insufficient for radiocarbon-dating were observed in the southeastern part of Structure 9.

Feature IV is composed of a loose concentration of rocks scattered over an area of roughly 3.40 x 2.30 m. Although the form and dimensions of the concentration may suggest a habitation structure, present evidence tends to indicate that the feature represents a dismantled cache.

4.3 Lithic Artifacts

The excavations produced a total of 7,721 lithic artifacts (Table 2). The overwhelming majority of the artifacts were associated with Level III (N: 6,392), followed by Level II (N: 996). Level I yielded 48 specimens and 85 others were surface-collected.

Table 2. Summary of the Lithic Collection

A. Class and Raw Material

Class	Raw Material									
	Chert	Quartzite	Quartz†	Slate	Metabasalt	Nephrite	Soapstone	Sandstone	Granite	Total
Chipped point	38	1	-	-	-	-	-	-	-	39

B. Provenience

Provenience	Tools		Flakes		Total	
	N	%	N	%	N	%
Structure 6	80	23.5	2,183	29.6	2,263	29.3
Structure 7	180	53.0	2,385	32.3	2,565	33.2
Structure 9	23	6.7	773	10.5	796	10.3
Feature IV	-	-	5	0.1	5	0.1
Interstructural Zones:						
Structure 6 - Feature IV	-	-	250	3.4	250	3.2
Structure 7 - Structure 8	50	14.7	1,678	22.7	1,728	22.4
Unknown	7	2.0	107	1.4	114	1.5
Total	341	100	7 382	100	7 723	100

Another 86 specimens were collected from an isolated humus lens underlying Level III in Structure 6. The provenience of 114 artifacts is unknown.

In terms of general distribution, the largest proportions of the collection were recovered from Structure 7 (33.2%), Structure 6 (29.3%) and the zone between Structures 7 and 8 (22.4%). Most of the specimens obtained from the latter zone were associated with the rock concentration partly overlain by Structure 7. Structure 9 was less productive, yielding 10.3% of the collection. The majority of these artifacts were found beneath the rocks forming the eastern segment of the tent ring. The zone separating Structure 6 and Feature IV and the excavated portion of the feature were low in artifact frequency.

The collection consists of 340 tools and tool fragments and 7,381 waste flakes. Major classes among the tools comprise point and knife forms, end scrapers, flake and microblade cores, microblades, retouched flakes and used flakes. Comparatively large numbers of biface fragments, polished fragments and tip-flute spalls, a small number of burin spalls, and a few blades and preforms were also recovered. Other tools in the collection include 3 hammerstones, 2 adzes, a burin, a burin-like tool, a side scraper and a drill.

The waste flakes are of various sizes and relate to all stages involved in the systematic production of lithic implements. Most, however, are small, suggesting relationships with the final stage of tool manufacturing.

Mottled black chert is by far the predominant raw material, representing 94% of the collection, followed by slate (2.21%), metabasalt (1.46%) and quartz (1.14%). The other raw materials, composed of quartzite, nephrite, soapstone, sandstone and granite, occur as fractions of a percentage.

4.4 Organic Remains

Organic remains recovered from the site comprise 813 animal bones and 16 charcoal samples (Appendix 3). All of the bones were associated with the lowest course in the rock concentration bordering Structure 7. Almost all are small fragments.

Seven of the charcoal samples were recovered from Structure 7 and 4 from deposits situated on the northern periphery of Structure 6. The other 5 samples were collected at different depths in the rock concentration mentioned above.

4.5 Radiocabon Dates

Two charcoal samples were submitted for dating to the Geological Sciences Radiocarbon Lab of Brock University, St. Catherines, Ontario. One of these samples was collected from the lowest layer of sand in the rock concentration and the other from a charcoal deposit associated with the Structure 7 mid-passage. The first sample provided an uncorrected radiocarbon date of 1910±80 B.P. (BGS 1517), or A.D. 40, while the second is dated to 1710±85 B.P. (BGS 1518), or A.D. 240.

Both dates are stratigraphically consistent and, along with the date of 50 B.C. obtained in 1990 for Structure 6, fall within the Middle period of the Dorset culture.

5.0 Preliminary Interpretations

The GhGk-63 site was occupied on a seasonal basis by Middle Dorset groups from the end of the last millenium B.C. into the 3rd century A.D. As presented in Avataq (1991:11), warm-weather occupation of the site is indicated by the tent rings. As also forwarded in that report, the distribution and dimensions of these habitation structures suggested multiple occupations by small groups composed of 1 or 2 nuclear families.

Re-occupation through time of the southern section of the site is confirmed by the radiocarbon dates, spanning a period of roughly 300 years. It is further demonstrated by the presence of lithic artifacts beneath rocks forming a part of Structure 9 and by the divisions in the rock concentration partially overlain by Structure 7. These data suggest 2 phases of occupation in the Structure 9 area and, minimally, 3 phases in the central excavation area.

The earliest components in the central area consist of Structure 6 and the lowest course of the rock concentration, radiocarbon-dated to 50 B.C. and A.D. 40, respectively. This phase was followed after an undetermined interval by the occupation associated with the middle course of the concentration. The third phase is represented by Structure 7, dated to A.D. 240, and the uppermost course of the concentration. The lithic artifacts contained in Level II might suggest a fourth, more recent phase. On the other hand, field observations tend to indicate that the artifacts found in the humus have been displaced from the underlying Level III by natural processes such as root action and erosion.

It is difficult at present to integrate the Structure 8 and 9 occupations into the above sequence. However, it is possible that Structure 8 may have been occupied during one or the other of the earlier phases. This suggestion is based on the relatively poor state of preservation of the tent ring which, as in the case of Structure 6, was probably disturbed by later occupants of the site. As well, since the phases identified in both excavation areas are associated with Level III, it is likely that the Structure 9 occupation components fall within the sequence in the central area.

The number and duration of the occupations encapsulated in the separate phases and the number of people involved in each occupation are unknown. However, the spatial relationships of the 4 excavated structures suggest that each was occupied at a different time. Single nuclear family habitations are indicated for Structures 6, 7 and 8 while the larger dimensions of Structure 9 imply occupation by an extended family or, perhaps, 2 families. Additionally, the low percentages of artifacts associated with

Structures 8 and 9 suggest short-term occupations, possibly of only several weeks duration. Similar brief occupations may be speculated for Structures 6 and 7. Also, the high percentage of artifacts present in the space covered by these 2 tent rings and the rock concentration suggests that this portion of the central excavation area was repeatedly and intensively occupied.

The functional classes in the lithic tool assemblage reflect a broad range of subsistence and domestic activities. Besides hunting, major activities carried out at the site included skinning and butchering, hide processing and the manufacturing of stone implements and cultural equipment in organic materials. Moreover, the overwhelming predominance of mottled black chert in the lithic collection signifies exploitation of the same raw material source by the different groups who occupied the site. This homogeneity of raw material suggests continuity of occupation through time by a local population.

Finally, while artifactual evidence is lacking, the form of the semi-subterranean dwellings suggest a Dorset origin for these habitations, which would have been occupied during cold-weather. Alternately, the food cache, the 2 features interpreted as caches and the lithic cache would have been prepared during warm-weather, probably in summer or fall. The latter 3 features are clearly related to Dorset occupation of the site. The cultural affiliation of the food cache is undetermined.

6.0 Discussion

Archaeological salvage excavations conducted in 1990 and 1991 at GhGk-63 covered a total of 127 m^2. Although this total represents only a small fraction of the site area, it is estimated that the greater portion of the cultural material contained in the site has been rescued. Consequently, no further excavations are recommended in the site.

The excavations were centred on 4 tent rings and yielded 12,235 lithic artifacts, including 644 tools. These results shed new light on the Dorset culture in southeastern Hudson Bay and, accordingly, analysis of the data is strongly recommended.

The importance of GhGk-63 resides in large measure on its geographic location and chronology of occupation. It is situated at the southernmost limit of the Dorset culture in eastern Hudson Bay as presently known and represents the only Middle Dorset occupation in the region confirmed by radiocarbon-dating. The few other Dorset sites excavated in the region are well-removed from Kuujjuarapik. The nearest of these sites are located at Richmond Gulf, on the Belcher Islands and at Inukjuak and, in all instances, date to either the Early or Late periods of the culture.

Also, the lithic collection recovered from the site is characterized by a high degree of quality and clarity in terms of composition and context. The structural associations of the artifacts and the functional classes included in the tool assemblage are well-defined, indicating various specific activity areas in the site. As well, a large number of stylistic attributes observed on the tools are of marked comparative value and allow for the study of Dorset technological development through time and space.

The analysis of the GhGk-63 site will contribute to a better understanding of the Dorset culture in southeastern Hudson Bay and, importantly, provide the community of Kuujjuarapik archaeological information of local interest. The Inuit of Nunavik are keenly aware of the cultural heritage importance of archaeological resources and over the years have actively promoted the protection and preservation of these resources for cultural and educational purposes. As now planned, the artifact collection and other data obtained from the GhGk-63 site will be displayed in the local community cultural transmission centre to be built eventually in Kuujjuarapik. Such displays, combined with textual reports, will foster a greater appreciation among the population of past Inuit lifeways, practices and values.

List of Organic Remains

Appendix 3. List of Organic Remains

A. Osteological Collection

M^2	Quadrant	Number of Bones
BW 55	NE	5
BW 55	SE	515
BW 55	NE	28
BW 55	NE	13
BW 56	SE	14
BY 55	NW	3
BY 55	NE	27
BY 56	SW	1
BZ 55	NE/SE	37
BU 56	NW	5
BU 56	NW	94
BU 56	NE/NW	26
BU 56	SW	15
BU 56	SW	2
BU 57	NW	2
BU 57	SW	2
BU 57	SE	24
	Total	813

All bones were collected in Level III.

B. Charcoal Samples

Sample No.	M^2	Quadrant
